CERTIFICATE OF ACCEPTANCE OF SOIL SURFACE

GEOSYNTHETIC INSTALLER

COMPANY Gundle Lining Const.
ADDRESS 19103 Gundle Rd
Houston TX
77073

PROJECT

LOCATION Underwood, ND
PROJECT Pond 93
OWNER Cooperative Power

I, the Undersigned, the duly authorized representative of Gundle Lining Const. Co.

do hereby accept the area of soil surface bounded by and covered by Panels P232 thru P244 in the south east corner of Pond 93. The approximate area is 60,996 sq ft.

and shall be responsible for maintaining its integrity and suitability in accordance with the project specifications from this date to the completion of the installation.

Project Number:	BFDX-92-019C	Sample Number:	DS 01
Project Description:	EP #93 Liner	Date Sampled:	8/8/92
Seam Number:	DS 01	Date Tested:	8/9/92
Welder Number:	-	Tested By:	Jon Austin

PRELIMINARY DATA SHEET

SEAM SHEAR TEST RESULTS:

Test Number	Shear Strength (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	124	80	FT
2	124	80	FT
3	123	80	FT
4	124	80	FT
5	125	80	FT
Average	124		

PEEL TEST RESULTS:

Test Number	Peel Strength at Failure (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	76	52	FT
2	80	52	FT
3	90	52	FT
4	78	52	FT
5	81	52	FT
Average	81		

THICKNESS TEST RESULTS:

Test Number	Thickness (inches)	Specifications (inches)	
1	43	0.040	
2	42	0.040	
3	43	0.040	
4	43	0.040	
5	43	0.040	
Average	43

H.D.P.E. LINER REPORTS

Project Number:	BFDX-92-019C	Sample Number:	DS 16
Project Description:	EP #93 Liner	Date Sampled:	8/8/92
Seam Number:	DS 16	Date Tested:	8/9/92
Welder Number:	-	Tested By:	Jon Austin

PRELIMINARY DATA SHEET

SEAM SHEAR TEST RESULTS:

Test Number	Shear Strength (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	126	80	FT
2	124	80	FT
3	122	80	FT
4	131	80	FT
5	128	80	FT
Average	126		

PEEL TEST RESULTS:

Test Number	Peel Strength at Failure (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	94	52	FT
2	92	52	FT
3	86	52	FT
4	92	52	FT
5	91	52	FT
Average	91		

THICKNESS TEST RESULTS:

Test Number	Thickness (inches)	Specifications (inches)	
1	41	0.040	
2	42	0.040	
3	41	0.040	
4	41	0.040	
5	42	0.040	
Average	41

Project Number:	BFDX-92-019C	Sample Number:	DS 30A
Project Description:	EP #93 Coal Creek	Date Sampled:	8/8/92
Seam Number:	DS 30A	Date Tested:	8/27/92
Welder Number:	-	Tested By:	JC

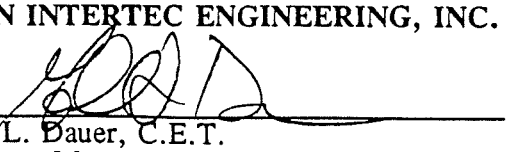
PRELIMINARY DATA SHEET

SEAM SHEAR TEST RESULTS:

Test Number	Shear Strength (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	122	80	FT
2	137	80	FT
3	121	80	FT
4	140	80	FT
5	128	80	FT
Average			

PEEL TEST RESULTS:

Test Number	Peel Strength at Failure (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	80	52	FT
2	94	52	FT
3	87	52	FT
4	104	52	FT
5	85	52	FT
Average			



THICKNESS TEST RESULTS:

Test Number	Thickness (inches)	Specifications (inches)	
1	.0402	.040	
2	.040	.040	
3	.0404	.040	
4	.040	.040	
5	.040	.040	
Average			

REMARKS:

HDPE LINER REPORTS

Project Number:	BFDX-92-019C	Sample Number:	DS 88
Project Description:	EP #93 Coal Creek	Date Sampled:	N/I
Seam Number:	DS 88	Date Tested:	8/24/92
Welder Number:	-	Tested By:	JC

PRELIMINARY DATA SHEET

SEAM SHEAR TEST RESULTS:

Test Number	Shear Strength (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	128	80	FT
2	132	80	FT
3	127	80	FT
4	130	80	FT
5	129	80	FT
Average			

PEEL TEST RESULTS:

Test Number	Peel Strength at Failure (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	91	52	FT
2	87	52	FT
3	87	52	FT
4	83	52	FT
5	87	52	FT
Average			

THICKNESS TEST RESULTS:

Test Number	Thickness (inches)	Specifications (inches)	
1	.0433	.040	
2	.0432	.040	
3	.0433	.040	
4	.0430	.040	
5	.0420	.040	
Average	.0431

Engineers and Scientists Serving the Built and Natural Environments

HDPE LINER REPORTS

Project Number:	BFDX-92-019C	Sample Number:	DSE 5
Project Description:	EP #93 Coal Creek	Date Sampled:	9/10/92
Seam Number:	DSE 5	Date Tested:	9/11/92
Welder Number:	-	Tested By:	JC

PRELIMINARY DATA SHEET

SEAM SHEAR TEST RESULTS:

Test Number	Shear Strength (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	131	80	FT
2	125	80	FT
3	131	80	FT
4	129	80	FT
5	129	80	FT
Average			

PEEL TEST RESULTS:

Test Number	Peel Strength at Failure (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	83	52	FT
2	81	52	FT
3	64	52	FT
4	73	52	FT
5	58	52	FT
Average			

THICKNESS TEST RESULTS:

Test Number	Thickness (inches)	Specifications (inches)	
1	.0419	.040	
2	.0419	.040	
3	.0417	.040	
4	.0419	.040	
5	.0418	.040	
Average	.0418		

REMARKS:

FT = Film Tear
BT = Bond Tear

RE: GEOMEMBRANE QUALITY ASSURANCE SERVICES, ASH POND 91 AND THE DRAINS POND, COAL CREEK STATION, UNDERWOOD, NORTH DAKOTA

Gentlemen:

Golder Construction Services, Inc. is pleased to present this report summarizing the quality assurance monitoring services performed for the installation of a geomembrane lining system at Ash Pond 91 and the Drains Pond, Coal Creek Station, Underwood, North Dakota. The quality assurance monitoring observations were performed from July 2, 1993 to September 20, 1993 and indicate that the installation of geomembrane liner for this effort is in substantial compliance with the specification guidelines and quality assurance program.

We appreciated the opportunity to work with Cooperative Power Association on this project. Should you have any questions or comments, please contact us.

Sincerely,

GOLDER CONSTRUCTION SERVICES, INC.

1.0 INTRODUCTION

Golder Construction Services, Inc. (GCS) under contract to Cooperative Power Association (CPA) has performed quality assurance (QA) observation and conformance testing for the construction of a geomembrane liner at Ash Pond 91 and the Drains Pond at the Coal Creek Station generating facility near Underwood, North Dakota. Specifically, this report provides a summary of our observations and testing associated with the installation of the geomembrane lining system installed over a 2-foot thick compacted clay liner system.

1.1 Background

Cooperative Power Association (CPA) and United Power Association (UPA) own and operate Coal Creek Station located near Underwood, North Dakota (Figure 1). Coal Creek Station is a two unit, 1100 megawatt lignite fueled power plant and is permitted as a zero discharge facility. The facility was constructed with two ash ponds, four evaporation ponds, a recycle pond, an extended basin for cooling water storage, and a river basin for storage of raw water. Since 1980, CPA has been remediating the existing pond clay liner systems by installing a geomembrane liner system over the clay liner. In October 1990, CPA completed construction of a 3.9 million square foot geomembrane liner in the Lower North Evaporation Pond (GCS, 1990). A 1.3 and 2.9 million square foot geomembrane liner was installed in Evaporation Ponds 92 and 94, respectively, during the period of July 1991 through October 1991 (GCS, 1991). During the period of August 1992 through September 1992, CPA completed the construction of a 2.9 million square foot geomembrane liner in Evaporation Pond 93 (GCS, 1992).

1.2 Project Description

Ash Pond 91 and the Drains Pond construction was accomplished using two primary contractors. Earthwork was performed by D.H. Blattner Construction (Blattner) of

Minneapolis, Minnesota. Geosynthetic installation was performed by Gundle Lining Systems, Inc. (Gundle) of Houston, Texas.

Quality assurance services during construction of the clay liner were performed independently by Braun Intertec Engineering, Inc. (Braun) of Bismarck, North Dakota. Surveying was performed by Interstate Engineering of Jamestown, North Dakota to ensure that design lines and grades were achieved prior to geomembrane deployment.

A summary of the geomembrane construction tasks is provided below:

- Installation of approximately 3.1 million square feet of 40 mil high density polyethylene (HDPE) geomembrane in Ash Pond 91; and
- Installation of approximately 350,000 square feet of 40 mil HDPE geomembrane in the Drains Pond.

1.3 Quality Assurance

GCS, a wholly owned subsidiary of Golder Associates, Inc. (Golder), was retained to provide full-time quality assurance services for installation of a geomembrane liner for Ash Pond 91 and the Drains Pond at Coal Creek Station. Specifically, the GCS scope of services involved the following items:

- Provide full-time, on-site personnel to observe construction activities and verification that the completed work complied with the specifications and plans for the project;
- Verification that the materials used in construction were within the construction specifications as developed by the designer;
- Preparation of record documentation of the construction, including daily summary reports with supporting data sheets and record drawings of the geomembrane lining system; and

- Preparation of this quality assurance report to summarize our observations and testing results.

1.4 Project Coordination

All QA activities were directed by Ron Uhle, P.E., the GCS Project Manager. A summary of the GCS QA staff which were on-site during the construction period is presented in Appendix A.

The GCS QA staff consisted of a lead monitor (Cliff Baker), two monitors from GCS, and one to two monitors provided by CPA. The total number of QA monitors typically varied from three to four as required by the Installer's level of effort. When available, QA monitors were utilized to enter monitoring data into an on-site computer and generate the record drawing for the final report preparation. The lead monitor or a designated QA monitor was on-site at all times during the installation process. QA monitoring by GCS began on July 2, 1993. The geomembrane installation was completed on September 20, 1993. The Installer typically worked an 8 to 10-hour shift, six days per week.

Construction scheduling issues and specification/design clarifications were discussed in a pre-construction meeting held on July 7, 1993. Minutes from this meeting are presented in Appendix B. Weekly construction coordination meetings were conducted throughout the construction period with representatives of CPA, GCS, Blattner, and Gundle. A listing of Gundle's installation personnel is presented in Appendix C-1.

1.4.1 Daily Construction Summary Reports

Photographic documentation and daily summary reports were prepared throughout the construction sequence to formally document the key elements of construction and the QA activities which occurred. Construction activities were discussed on a weekly basis between GCS on-site QA personnel and the GCS Project Manager. In addition, daily observation

reports were prepared by all QA field personnel and submitted to the lead monitor. The on-site lead monitor prepared weekly summary reports which were submitted to the CPA Project Manager (Jim Martin). Daily observation reports and documenting photographs are not included in this report, but are available for review at Coal Creek Station or at the GCS office in Lakewood, Colorado.

1.5 Project Specifications

All work was performed according to the design plans and specifications, which are presented in the following documents:

- "Contract for 1992 Liner Installation for Evaporation Pond 93 and Ash Pond 91, Coal Creek Station", prepared by CPA and UPA, dated January 10, 1992;
- "Construction Drawings for 1992 Ash Disposal, Coal Creek Station", prepared by CPA, dated January 1992;
- "Quality Assurance Manual for the Installation of Polyethylene Lining Systems", prepared by Gundle, dated July 1990; and
- "NSF 54 - Flexible Membrane Liners", prepared by National Sanitation Foundation, dated May 1991.

2.0 IN-PLANT MONITORING OF GEOMEMBRANE MATERIALS

In 1992, Gundle manufactured approximately 6.75 million square feet of 40 mil HDPE geomembrane for Ash Pond 91 and Evaporation Pond 93. Gundle manufactured the HDPE geomembrane on an intermittent basis between March 23, 1992 and April 9, 1992. Monitoring of the HDPE geomembrane production was performed by GCS on a part-time basis at the Gundle manufacturing facility in Houston, Texas. The plant monitoring was authorized by CPA to provide documentation that the geomembrane met the project specifications prior to shipment to the site.

A total of 301 rolls of HDPE geomembrane were approved for shipment to the construction site. In-Plant Geomembrane Roll Quality Assurance Records for all rolls produced for Ash Pond 91 and Evaporation Pond 93 are presented in the QA report for Evaporation Pond 93 (GCS, 1992).

2.1 Scope of Work

Quality assurance activities conducted by GCS during the plant visits consisted, in general, of the following:

- Spot thickness measurements were obtained on rolls produced during GCS plant visits;
- Thickness measurements performed by Gundle on rolls produced while GCS was not at the plant were reviewed;
- The condition of the sheet was visually observed for defects including dimples, creases, undispersed raw materials, etc.;
- Date and time of roll manufacturing were documented;
- Inventory of rolls accepted and rejected by roll number was documented;

- Gundle geomembrane roll quality control and assurance certificates and resin quality control certificates for the accepted rolls were obtained and reviewed for conformance to the project specifications; and

- GCS selected rolls for conformance testing. Conformance samples were subsequently cut and sent to the GCS geosynthetics laboratory in Atlanta, Georgia.

2.2 In-Plant Monitoring Observations

A GCS monitor was at the plant on a part-time basis during production of the geomembrane rolls produced for Ash Pond 91 and Evaporation Pond 93. Therefore when GCS was at the plant, a portion of the rolls were approved or rejected by GCS and Gundle, and the remainder of the rolls were approved or rejected solely by Gundle when GCS was not at the plant.

For approved rolls, all spot thickness measurements met the project specifications and no major defects were observed during visual monitoring of the sheet during production. Each roll measured 34.5 feet wide by approximately 650 feet long. The base resin materials used during manufacturing were supplied by Quantum Chemical Corporation, Solvay Polymers, and Chevron Chemical Company.

2.3 Review of Geomembrane Quality Control Documents

Quality control documents submitted by Gundle included HDPE polymer resin quality control certificates, geomembrane roll quality control certificates, and welding rod quality control certificates. Documents were reviewed to verify that the required quality control testing frequency and the material property requirements stated in the project specifications were met.

2.3.1 Resin Quality Control Certificates

Polymer raw material certificates were provided by the resin manufacturer at a frequency of one per rail car shipment. These certificates were reviewed to verify that the density and melt index of the materials met the requirements of the project. A copy of each resin quality control certificate for geomembrane used in Ash Pond 91 and the Drains Pond is presented in Appendix C-2.

2.3.2 Roll Quality Control Certificates

Roll quality control and assurance certificates were reviewed to verify conformance of the materials to the requirements of the project. For rolls used in Ash Pond 91 and the Drains Pond, a copy of each roll quality control or assurance certificate is presented in Appendix C-3.

2.3.3 Welding Rod Quality Control Certificates

Welding rod certification included the quality control certificates for the rod and the resin used to make the rod. The welding rod quality control certificates are presented in Appendix C-4.

2.4 Conformance Testing

Conformance test samples were selected by GCS QA personnel and removed by Gundle at the manufacturing plant at a frequency of approximately one per 100,000 square feet of geomembrane material delivered to the project. Sixty-nine rolls of the 40 mil HDPE geomembrane were sampled and tested for conformance with the project specifications (Appendix D-1). The testing frequency resulted in approximately one test per 97,800 square feet of delivered geomembrane, which exceeded the minimum project requirements of one test per 100,000 square feet. Conformance testing was performed by the GCS geosynthetic

laboratory located in Duluth, Georgia. Results of the conformance tests for geomembrane used in Ash Pond 91 and the Drains Pond are presented in Appendix D-2. Test results indicated that all of the geomembrane materials delivered to the site met or exceeded the project's required material properties.

3.0 RESULTS OF GEOMEMBRANE INSTALLATION QUALITY ASSURANCE TESTING AND MONITORING

Quality assurance activities conducted during the installation of the geomembrane consisted, in general, of the following:

- Observation of the underlying surface;
- Observation and documentation of HDPE geomembrane deployment and measurement of sheet thickness;
- Observation of pre-weld sample testing and documentation of results supplied by Gundle;
- Observation and documentation of field seams prior to and following seaming;
- Location, testing, and documentation of seam strength destructive test samples; and
- Observation and documentation of non-destructive seam continuity testing.

A detailed description of each of the above activities is presented in the following sections.

3.1 Geomembrane Deployment

Geomembrane panels were visually monitored by GCS personnel as they were deployed from the roll into position on the subgrade. This process required the monitoring of subgrade conditions, sheet anchoring, sheet alignment, sheet overlap with adjacent panels, panel extensions into anchor trenches, sheet surface quality and sheet thickness. Each deployed geomembrane panel was assigned a unique identification number by a GCS monitor and each panel was visually monitored for damage and/or manufacturing imperfections. Defects were marked and documented by GCS monitors and subsequently repaired by Gundle.

Prior to geomembrane deployment, GCS QA personnel and Gundle verified that the surface to be lined had been rolled and compacted so as to be free of irregularities, protrusions, loose soil, and abrupt changes in grade; did not contain stones which may be damaging to the geomembrane; and did not contain shrinkage cracks or areas softened by high water content. Gundle certified in writing that the surface on which the geomembrane would be installed was acceptable. The subgrade acceptance certificates are presented in Appendix E.

The panels were deployed in general conformance with the HDPE panel layout as supplied by Gundle prior to deployment. The record drawings showing the approximate location of the Ash Pond 91 and the Drains Pond geomembrane panel layouts are presented on Figures 2 and 3, respectively.

The thickness monitoring program included measuring the sheet thickness using a machinist's micrometer at five locations across the lead and trail edge of each roll of material. At times, additional panel edge thicknesses were also measured at the discretion of the GCS QA monitor to confirm that the geomembrane used on the project was 40 mil and within project specifications.

The length of each panel was measured by GCS personnel using a measuring wheel. GCS personnel also recorded the panel length of each panel. The panel lengths recorded were approximate and did not reflect any trimming or adjustments for final placement. All lengths were measured from the inboard crest of the anchor trench.

GCS personnel observed the surface of each panel. Any defects or blemishes noted were recorded and were also reported to Gundle for corrective action.

The overlap of each panel with adjacent panels was also observed to verify that overlap was sufficient for seaming. Insufficient overlap areas were brought to the attention of Gundle for correction.

After deployment, Gundle placed loads of sandy cover material with a front end loader and sand bags along panel edges as a temporary loading measure until the panels were joined by fusion welding. Sandbags were similarly used to temporarily secure panels which extended into the anchor trenches a minimum of 5 to 6 feet.

A summary of abbreviations used by the GCS monitors during construction is presented in Appendix F. Deployment observations are presented in Appendix G.

3.2 Geomembrane Seaming

The principal seaming method for this project was the Gundle double wedge fusion weld. The fusion seaming (welding) process of the geomembrane liner ran concurrently with deployment. Extrusion welds were allowed during the seaming of the geomembrane for repairs and in areas where double wedge fusion welding was not practical. Monitoring of the seaming techniques consisted of visual observation of trial seam tests, monitoring ambient and seaming equipment temperatures, monitoring speed of seaming equipment, and continuous visual observation of completed seams.

3.2.1 Trial Seam Monitoring

Trial seams were performed as a means of monitoring the performance of the seaming apparatus and operator under actual site conditions. Trial seams were made by each welding apparatus/operator combination prior to the beginning of each day's seaming operation and at mid-day intervals during the seaming period. Samples were cut from the trial seams and quantitatively tested using a field tensiometer. Each trial seam was tested twice for peel adhesion (peel) and once for bonded seam strength (shear), with the untested portion of each sample retained for the archives of CPA at Coal Creek Station. GCS personnel observed the testing of pre-weld samples and documented the test results. The tensile testing of specimens taken from pre-weld samples was observed to verify that specimens did not fail

within the seam (film tear bond). GCS personnel verified that retesting was conducted in the event of a failing test.

One of the trial seams failed the pre-weld field testing. The welder and welding apparatus associated with the failed seams were not allowed to weld on the liner until passing trial seams were made in accordance with the project specifications. The trial seam results are presented in Appendix H.

3.2.2 Seam Procedures and Observations

Seaming operations were observed by the GCS QA monitors on a full-time basis. GCS personnel observed seams before and after welding. Each seam lap was checked for adequate overlap prior to seaming and also to verify that the seam area was clean and dry. Any concerns were brought to the attention of Gundle.

Personnel performing the seaming and the equipment used were recorded during monitoring for tracking purposes in the event of a destructive test failure. Following the completion of seaming and routine repair work, the full length of each seam was observed to verify that no additional repairs were required. All seams were inspected for visual quality and seam completion. Weld imperfections were marked by GCS and were subsequently repaired by Gundle in accordance with the specifications and Gundle QA manual.

The results of observations before and after seaming were recorded by GCS personnel. Seaming observations for fusion and extrusion welding are presented in Appendices I and J, respectively.

3.2.3 Geomembrane Defect and Repair Observations

Geomembrane panels were initially observed for damage which could have occurred during transportation and/or deployment as discussed in Section 3.1. All panels and seams were

repeatedly observed for defects until the cover material was placed over the geomembrane layer.

Each defect was documented, assigned a unique identification defect code, marked for repair by GCS on the geomembrane, and subsequently repaired by Gundle. Summaries of defects and non-destructive testing of repairs, including the approximate location of each repair, are presented in Appendix K.

3.3 Destructive Testing

In accordance with the project specifications, destructive samples were obtained from the seams of the geomembrane at a frequency of one destructive test sample per 500 linear feet of weld. The test locations were selected by GCS personnel based either on the completion of approximately 500 feet of welding by a given machine and/or welder, working conditions, or on seaming observations (e.g. suspicion of a defective weld).

A total of 25 and 222 destructive samples were obtained from the Drains Pond and Ash Pond 91 geomembrane liner, respectively, and were tested in Braun's geosynthetic laboratory, located in Bismarck, North Dakota, in accordance with ASTM D-638.

From each sample taken to the laboratory, ten specimens (1-inch wide) were removed for testing. Five specimens were tested for adhesion (peel) with the specified acceptance criteria being that five out of the five specimens must have yield strengths of at least 52 pounds per inch and fail in a film tear bond (FTB). For fusion welding, peel tests were performed on the inside weld track. Five specimens were also tested for bonded strength (shear) with the specified acceptance criteria being that five out of the five must have yield strengths greater than 80 pounds per inch and fail in a FTB.

In the event of a failing sample, the path of the welder or welding machine was traced in each direction from the failed destructive location at approximately 10-foot intervals. The

failing seam would then be bounded by passing destructive tests or the entire seam would be reconstructed. If the first alternative was adopted, the welder's path was capped with another layer of 40 mil HDPE then extrusion welded between the two passing locations. If the second alternative was adopted, the seam was then reconstructed by extrusion welding the outside track of the fusion weld.

The location of each destructive test sample is presented on the record drawings (Figures 2 and 3) and is identified on repair summaries (Appendix K). Failure modes for test specimens were reported based on the pass/fail codes shown on Figures 4 and 5. A summary of destructive test results is presented in Appendix L.

3.4 Non-destructive Testing

The non-destructive seam continuity testing was performed by Gundle and observed by GCS personnel. The non-destructive testing included pressure testing of double fusion welded seams and vacuum box testing of the extrusion welded seams. Documentation summarizing observation of the continuity testing is included on the fusion welding summaries (Appendix I) and the repair summaries (Appendix K).

4.0 CONCLUSIONS

Golder Construction Services, Inc. was retained by Cooperative Power Association to perform quality assurance observation and conformance testing for the construction of a geomembrane liner at Ash Pond 91 and the Drains Pond at the Coal Creek Station generating facility near Underwood, North Dakota. The quality assurance monitoring and testing program covered by this work included:

- On-site quality assurance monitoring and testing of geosynthetic installation;
- Verification that all geosynthetic materials used in construction were within specifications as developed by the designer of the facility; and
- Preparation of the construction documentation report, including field report summaries, test data summaries, and record survey drawings, written and signed by a North Dakota Registered Professional Engineer.

The results of testing and observations made by Golder Construction Services, Inc. while monitoring the construction of Ash Pond 91 and the Drains Pond indicated that the installation of the geomembrane materials was performed in substantial compliance with the project plans, specifications, and quality assurance program.

PROJECT: 937-4207

RE: PRE-CONSTRUCTION MEETING MINUTES FOR GEOMEMBRANE INSTALLATION AT POND 91 AND DRAINAGE POND, COAL CREEK STATION

A preconstruction meeting was held with Gundle Lining Construction Corp. at the Coal Creek Station construction office on July 7, 1993. The meeting began at 10:00 a.m. Mr. Jim Martin of Cooperative Power presided over the meeting. The purpose of the meeting was to discuss project organization, schedule, manpower, Gundle construction methods, project Quality Assurance QA requirements, project safety, and working rules at the Coal Creek Station. Minutes from the meeting are presented as follows:

Introductions were made with the following persons in attendance:

Jim Martin, CPA (on-site construction supervisor)
Dave O'Sadnick, GCS (Project Manager)
Cliff Baker, GCS (Resident Manager)
Jeff Iorio, GCS (Monitor)
Scott Hutsell, GCS (Monitor)
David Herreth, Gundle
Leroy Kautz, Interstate
John Kaiser, Interstate
Myron Colton, Braun Intertec
Ralph Lipelt, D.H. Blattner Construction
Kit Blattner, D.H. Blattner Construction

The scope of work includes the installation of about 66 acres of 40-mil HDPE in Pond 91 and about 10 acres of 40-mil HDPE in the plant drainage pond.

Jim Martin will be the focal point of all on-site communications. Andy Stewart, with CPA is the overall project manager.

In-plant monitoring was performed by GCS in the spring of 1992. All rolls shipped to the site have been pre-approved. GCS only has to perform roll inventory to verify that the rolls approved for shipment to the site were the same as those approved at the plant.

There should be enough 40 mil HDPE on site to complete the two ponds, even with the minor design changes made.

GCS described their role in the project as the third party QA consultant as per section 1.04 of the specifications. Specifically, GCS will:

- Provide one lead monitor (Cliff Baker) and two additional on-site monitors during installation. Three to four other monitors will be supplied by CPA;
- Monitor installation of geomembrane including deployment, material, and seam quality;
- Monitor and document non-destructive seam testing;
- Perform roll inventory and assurance that roll certificates match materials on-site;
- Monitor and document all geomembrane repairs and testing of repairs;
- Monitor and document all destructive tests of completed seams performed by Braun Intertec;
- Interpret and report geomembrane trial seam and destructive test results;
- Prepare a record drawing of the panel layout; and
- Prepare a final report documenting the installation of the 40-mil HDPE geomembrane.

A progress/safety meeting will be held each Thursday at 10:45 a.m. followed by a weekly construction meeting. Informal daily meetings will be held at the start of each working day somewhere near the construction area.

Any safety concerns should be reported to Jim Martin or any on-site CPA representative. An EMT and ambulance are on-site 24 hours a day and available at all times. To contact them, anyone can call security or contact any contractor on-site who has a radio. The contractors should limit access of their personnel to their own construction areas as much as possible for safety reasons since there is a large amount of activity at the site.

GCS will set up cones to mark areas where QA procedures have been completed. All personnel on-site will take care not to enter these areas or move the cones.

Non-destructive air pressure tests will be performed by pressurizing the seam between 25 and 30 psi for five minutes. A pressure loss of 3 psi or less will indicate an acceptable weld.

During non-destructive testing with the vacuum box, the vacuum will be held for a minimum of five seconds.

If a hot wedge seam is not acceptable, as determined from destructive or non-destructive testing, Gundle will locate and cap the faulty area using extrusion methods.

Protective layer sand will be placed in the center area of a panel soon after deployment to help protect against wind damage to the liner.

A single roll will be designated as patch material as specified. CPA will buy this roll as a separate cost item.

Braun Intertec will perform destructive sample testing. If any coupon from the test results fail, the section of seam that fails will be capped or reconstructed. Gundle will perform a field test using an on site tensiometer before sending samples to Braun.

Gundle agreed to weld through the anchor trench. Repairs will be made to the crest of the anchor trench. QA monitoring and testing will be made to the top crest of the interior slope of the pond.

Gundle was reminded that the specifications state that the liner shall be at least 40-mil thick with no exceptions. If any thickness values of less than 40 mil are measured by GCS, the values will be brought to the attention of CPA who will determine if that panel is acceptable.

Hard hats, safety glasses and shirts with sleeves will be required for all workers. Steel-toed shoes are not required.

CPA requested that Gundle supply them with any material safety data sheets (MSDS) for any of their construction supplies.

Gundle will have eight technicians, one supervisor (Al Kern) and a quality control officer (Mike Ruggerio). They will hire local labor as needed.

Gundle will have on site three fusion welding devices, at least two extrusion welding devices, two vacuum boxes and three pressure test devices.

Gundle will number all panels during deployment.

Gundle will use yellow markers on the liner, GCS will use white colored markers. Spray paint will not be used on the liner.

Gundle indicated that the work schedule will consist of 6 days per week, 10 hours per day with specific days and hours depending on weather delays.

Any work to be done on Sunday or a holiday has to be approved ahead of time through D.H. Blattner Const.

Work is scheduled to begin July 13, 1993. Pending weather.

The meeting adjourned at 11:15 a.m.

This letter will certify that the Marlex* resin shown below, as supplied by Phillips 66 Company, conforms to our manufacturing specification.

Type:	K304
Lot Number:	7130369
P.O. Number:	S021569
Date shipped:	05/10/93
Package:	PGPX 5776
Quantity:	176800 lbs.
Melt Index:	.12 gm/10 min.
Density:	.939 gm/cc

SUBGRADE ACCEPTANCE CERTIFICATES

Gundle®

SUBGRADE SURFACE ACCEPTANCE

PROJECT: Co-op JOB NUMBER: G147

LOCATION: Underwood ND DATE: 9-20-93

I, the undersigned duly authorized representative of Gundle Lining Construction Corporation, certify that upon visual inspection the subgrade surface described below meets criteria for installation of a 40 mil flexible membrane liner. By signing below, however, Gundle acknowledges no responsibility for the subgrade design, degree of moisture or compaction, integrity, elevation, or maintenance thereof, in any way.

Approximate size of area: 348,000

Description of area: DRAINS POND - INCLUDES SLOPES + ALL FLOOR.

GUNDLE REPRESENTATIVE | OWNER/CONTRACTOR | INSPECTOR

APPENDIX J-1

EXTRUSION WELDING SUMMARY - DRAINS POND

November 1993

937-4207

Golder Construction Services, Inc.

There is no extrusion welding summary for the Drains Pond
because all extrusion welded seams were associated with repairs (Appendix K-1).

APPENDIX J-2

EXTRUSION WELDING SUMMARY - ASH POND 91

H.D.P.E. Liner Reports

Project Number: BFDX-93-019C
Project Description: AEP #93 91 Coal Creek
Seam Number: P 7/8
Welder Number: 1061

Sample Number: DS-1
Date Sampled: 7/20/93
Date Tested: 8/4/93
Tested By: L. Larson

PRELIMINARY DATA SHEET

SEAM SHEAR TEST RESULTS:

Test Number	Shear Strength (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	121	80	FT
2	127	80	FT
3	132	80	FT
4	125	80	FT
5	126	80	FT
Average			

PEEL TEST RESULTS:

Test Number	Peel Strength at Failure (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	85	52	FT
2	85	52	FT
3	87	52	FT
4	89	52	FT
5	84	52	FT
Average			

THICKNESS TEST RESULTS:

Test Number	Thickness (inches)	Specifications (inches)	
1	.0430	0.040	
2	.0420	0.040	
3	.0418	0.040	
4	.0416	0.040	
5	.0418	0.040	
Average	.0420		

REMARKS:

FT = Film Tear
BT = Bond Tear

H.D.P.E. Liner Reports

Project Number: BFDX-92-019C
Project Description: AP #91 Coal Creek
Seam Number: 46/49
Welder Number: 10

Sample Number: DSE-1
Date Sampled: N/I
Date Tested: 8/13/93
Tested By: J. Cadotte

SEAM SHEAR TEST RESULTS:

Test Number	Shear Strength (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	129	80	FT
2	124	80	FT
3	130	80	FT
4	126	80	FT
5	131	80	FT
Average			

PEEL TEST RESULTS:

Test Number	Peel Strength at Failure (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	65	52	FT
2	46	52	FT
3	61	52	FT
4	44	52	FT
5	59	52	FT
Average			

THICKNESS TEST RESULTS:

Test Number	Thickness (inches)	Specifications (inches)	
1	.042	0.040	
2	.042	0.040	
3	.042	0.040	
4	.042	0.040	
5	.042	0.040	
Average	.042

H.D.P.E. Liner Reports

Project Number: BFDX-92-019C
Project Description: AP #91 Coal Creek
Seam Number: 82/89
Welder Number: 1053

Sample Number: DS-57
Date Sampled: 8/19/93
Date Tested: 8/23/93
Tested By: J. Cadotte

SEAM SHEAR TEST RESULTS:

Test Number	Shear Strength (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	125	80	FT
2	127	80	FT
3	129	80	FT
4	127	80	FT
5	123	80	FT
Average			

PEEL TEST RESULTS:

Test Number	Peel Strength at Failure (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	92	52	FT
2	102	52	FT
3	95	52	FT
4	91	52	FT
5	98	52	FT
Average			

THICKNESS TEST RESULTS:

Test Number	Thickness (inches)	Specifications (inches)	
1	.0445	0.040	
2	.0445	0.040	
3	.0445	0.040	
4	.0445	0.040	
5	.0445	0.040	
Average	.0445

H.D.P.E. Liner Reports

Project Number: BFDX-92-019C
Project Description: AP #91 Coal Creek
Seam Number: 184-185
Welder Number: 1066

Sample Number: DS-116
Date Sampled: 9/1/93
Date Tested: 9/9/93
Tested By: M. Colton

SEAM SHEAR TEST RESULTS:

Test Number	Shear Strength (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	127	80	FT
2	131	80	FT
3	130	80	FT
4	126	80	FT
5	129	80	FT
Average			

PEEL TEST RESULTS:

Test Number	Peel Strength at Failure (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	76	52	FT
2	72	52	FT
3	72	52	FT
4	75	52	FT
5	83	52	FT
Average			

THICKNESS TEST RESULTS:

Test Number	Thickness (inches)	Specifications (inches)	
1	.041	0.040	
2	.041	0.040	
3	.041	0.040	
4	.042	0.040	
5	.040	0.040	
Average	.041

H.D.P.E. Liner Reports

Project Number: BFDX-92-019C
Project Description: AP #91 Coal Creek
Seam Number: 193-194
Welder Number: 1054

Sample Number: DS-129
Date Sampled: 9/3/93
Date Tested: 9/9/93
Tested By: M. Colton

SEAM SHEAR TEST RESULTS:

Test Number	Shear Strength (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	128	80	FT
2	128	80	FT
3	126	80	FT
4	125	80	FT
5	127	80	FT
Average			

PEEL TEST RESULTS:

Test Number	Peel Strength at Failure (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	80	52	FT
2	90	52	FT
3	90	52	FT
4	72	52	FT
5	82	52	FT
Average			

THICKNESS TEST RESULTS:

Test Number	Thickness (inches)	Specifications (inches)	
1	.040	0.040	
2	.040	0.040	
3	.040	0.040	
4	.040	0.040	
5	.040	0.040	
Average	.040

H.D.P.E. Liner Reports

Project Number: BFDX-92-019C
Project Description: AP #91 Coal Creek
Seam Number: 263/264
Welder Number: 1066

Sample Number: DS-186
Date Sampled: 9/14/93
Date Tested: 9/18/93
Tested By: M. Colton

SEAM SHEAR TEST RESULTS:

Test Number	Shear Strength (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	116	80	FT
2	116	80	FT
3	106	80	FT
4	114	80	FT
5	115	80	FT
Average			

PEEL TEST RESULTS:

Test Number	Peel Strength at Failure (lbs./in.)	Specifications (lbs./in.)	Failure Type
1	86	52	FT
2	79	52	FT
3	101	52	FT
4	84	52	FT
5	89	52	FT
Average			

THICKNESS TEST RESULTS:

Test Number	Thickness (inches)	Specifications (inches)	
1	.0404	0.040	
2	.0405	0.040	
3	.0406	0.040	
4	.0406	0.040	
5	.0406	0.040	
Average	.0405

Notes:

Permeability tests performed on undisturbed samples collected from the liner in Shelby tubes.

Permeability results from falling head tests performed by Braun Intertec.

Notes:

Reference: Cooperative Power Association, 1993 "Final Construction Report, Evaporation Pond 93 and Ash Pond 91"

The break strength, yield strength, break elongation, and yield elongation (ASTM D638) are each an average of one test in the machine direction and one test in the transverse direction.

1 Introduction

In 2015, the United States Environmental Protection Agency (US EPA) published a final rule to regulate the disposal of coal combustion residuals (CCR) (US EPA, 2015). This rule (herein called the "CCR Rule") established criteria for liner systems to determine whether surface impoundments were lined or unlined. Impoundments classified as unlined were subject to closure requirements. Based on these criteria, a lined surface impoundment was required to have a liner system that met one of the following requirements.

- "A liner consisting of a minimum of two feet of compacted soil with a hydraulic conductivity of no more than 1×10^{-7} cm/sec" [40 CFR 257.71(a)(1)(i)];
- A composite liner system with "the upper component consisting of, at a minimum, a 30-mil geomembrane liner (GM), and the lower component consisting of at least a two-foot layer of compacted soil with a hydraulic conductivity of no more than 1×10^{-7} centimeters per second (cm/sec). GM components consisting of high density polyethylene (HDPE) must be at least 60-mil thick" [40 CFR 257.70(b)]; or
- An alternative composite liner system with "the upper component consisting of, at a minimum, a 30-mil GM, and a lower component, that is not a geomembrane, with a liquid flow rate no greater than the liquid flow rate of two feet of compacted soil with a hydraulic conductivity of no more than 1×10^{-7} cm/sec. GM components consisting of high density polyethylene (HDPE) must be at least 60-mil thick" [40 CFR 257.70(c)].

In August 2018, the United States Court of Appeals for the District of Columbia vacated portions of the CCR Rule related to the liner criteria. The Court decision was based on information contained in US EPA's 2014 Human and Ecological Risk Assessment of Coal Combustion Residuals (US EPA, 2014), which indicated that clay-lined impoundments were more likely to leak than composite-lined impoundments. As a result, the Court found that only composite-lined systems, as described in 40 CFR 257.70(b), meet minimum federal liner standards. Consequently, some impoundments that were formerly considered lined do not meet federal standards and are subject to closure requirements. This means that some impoundments that meet all CCR Rule requirements related to groundwater protections standards, location standards, and safety factor requirements may be required to close.

The objective of this report is to present an approach to evaluate the performance of liner systems and show that under certain conditions, alternative liners perform comparably to, if not better than, a composite liner. The CCR Rule specifies that flow through a clay or the compacted soil portion of a liner system is to be evaluated using Darcy's Law (Eqn. 1 and 3 in Section 2); this report details a methodology to evaluate flux and travel times through both the GM and clay layers in a liner system. Performance is assessed using two metrics: the hydraulic flux that is expected to migrate through a liner system and the travel time required for fluids to migrate through a liner system. Using the approach presented in this report, one can compare the performance of composite-lined systems with other liner systems that do not meet current liner criteria.

Section 2 of this report presents a general methodology for quantifying the rate of hydraulic flux and estimating travel times through various liner systems. Section 3 presents two examples of the methodology comparing the performance of a composite liner system to alternative liner systems.

Section 4 discusses the data that are necessary to credibly demonstrate that a natural clay liner is effective and performs comparably to a composite liner. Finally, Section 5 concludes by identifying the comparative methodology that a Qualified Professional Engineer (QPE) can employ, including hydraulic flux rate and travel time through the liner, to demonstrate that alternative liner systems can perform as well as, if not better than, composite liners as defined by 40 CFR 257.70(b).

2 Surface Impoundment Liner Performance Evaluation Methodology

This section presents an approach to evaluate and compare the performance of surface impoundment liner systems. Two metrics, hydraulic flux (*i.e.*, volume of fluid passing through the liner per unit area per unit time) and fluid travel time across the liner thickness, are used to define liner performance. Hydraulic flux governs how much mass ultimately gets into underlying groundwater, while travel time is a metric for immediacy of potential risks.

2.1 Hydraulic Flux

The flow of water through a liner system (*e.g.*, hydraulic flux) is one metric that can be used to evaluate performance. Hydraulic flux through a liner is a surrogate for constituent mass that may be escaping a disposal facility and impacting underlying groundwater. This section presents a methodology for estimating hydraulic flux through a clay liner system and a composite liner system. The methodology presented to calculate hydraulic flux through a clay lined system is appropriate both for engineered clay liners and natural clay liners.

2.1.1 Clay-Lined Systems

Darcy's Law describes the flow of a liquid moving through a layer of saturated soil (Freeze and Cherry, 1979, Eq. 2.5). This equation can also be used to describe flow through a clay liner system (Eqn. 1):

$$Q_c = k_s i_s A \qquad \text{Eqn. 1}$$

where:

Q_c = Flow rate in clay layer (L^3/T);
k_s = Saturated hydraulic conductivity (L/T);
i_s = Hydraulic gradient (unitless); and
A = Surface area (L^2).

In this scenario, the hydraulic conductivity, k_s, describes the ability of water to move through the liner matrix. Thus, it is a function of both liner (*e.g.*, soil) and fluid properties, including the size and shape of the liner soil particles, as well as fluid density and viscosity (Bear, 1979). Hydraulic gradient, i_s, is the change in hydraulic head over distance in the direction of flow. For vertical flow through a clay liner system, the hydraulic gradient is calculated as follows (Touze-Foltz *et al.*, 1999, Eq. 2):

$$i_s = \frac{h + t_s - h_a}{t_s} \qquad \text{Eqn. 2}$$

where:

h = Pressure head of the liquid on top of the liner (L);
h_a = Pressure head underlying the liner (L); and

t_s = Thickness of the liner (L).

Presence of a pressure head underlying a liner, h_a, creates resistance to downward seepage. In scenarios where soils underlying the liner are unsaturated (*i.e.*, zero hydraulic pressure at the base of the liner), h_a is set to 0. In these situations, the gravity-driven specific discharge in a saturated clay liner can be quantified by the following equation:

$$q = \frac{Q_c}{A} = k_s(\frac{h}{t_s} + 1) \quad \text{Eqn. 3}$$

where:

q = Specific discharge, which is the unit flow rate per area across the liner (L/T).

Specific discharge, q, divided by the effective porosity is seepage velocity, which describes the rate at which a fluid moves through a porous media.

It is important to note that the ability of a fluid to flow through an unsaturated or partially saturated environment is impeded relative to flow through saturated environments. This is because in a multi-fluid system, fluids (in this case, air and water) compete for pore space, resulting in reduced mobility for all fluids (Cohen and Mercer, 1993). Darcy's Law presented above is valid for fully saturated environments, which is likely appropriate for relatively thin, engineered clay liner systems during the period of the surface impoundment operation. However, for natural clay environments, clay layers are often much thicker than engineered clay liners. In these circumstances, it is inappropriate to assume that the entire natural clay liner is fully saturated and, thus, Darcy's equation must be adjusted to account for the lower water saturation level in the natural clay liner. The equivalent Darcy's equation for vertical unsaturated flow in porous media can be written as (Bear, 1979):

$$q = k_r \times k_s \times (\frac{\partial \psi}{\partial z} + 1) \quad \text{Eqn. 4}$$

where:

$\partial \psi / \partial z$ = Vertical pressure head gradient in the unsaturated seepage zone; and
k_r = Relative permeability of the clay liner.

Relative permeability varies from 0 to 1 depending on the level of saturation. Multiple models and approaches are available for estimating relative permeability as a function of moisture content or saturation (*e.g.*, Brooks and Corey, 1964; van Genuchten, 1980).

2.1.2 Composite-lined Systems

A composite liner, as defined in 40 CFR 257.70(b), consists of two components: an upper GM liner of at least 30 mil and the lower layer of compacted soil at least two feet deep with a hydraulic conductivity of no more than 1×10^{-7} cm/sec. GM components consisting of HDPE must be at least 60 mil thick. GM liners are effectively impermeable to flow; therefore, hydraulic flux through a composite liner occurs primarily *via* defects in the liner. GM defects, which may be a result of manufacturing, installation, or weathering, provide preferential pathways for water flow through the GM. There are two approaches, described below, that can be used to estimate hydraulic flux through defects in a composite liner. Both approaches assume that the hydraulic system is at steady state, the soil liner is saturated, and flow is vertical.

2.1.2.1 Giroud's (1997) Formula for Flux Through a Circular Defect

Giroud (1997, Eq. 20) presented a semi-empirical approach to calculate flow through a defect in a composite liner. Previous studies have evaluated flow through a wide range of GM defects, including circular defects, square and rectangular defects, infinitely long defects, and defects in GM wrinkles caused by thermal expansion (Giroud, 1997; Giroud *et al*., 1997; Touze-Foltz *et al*., 1999). This report presents only the approach to calculate flow through a circular GM defect (Eqn. 5).

$$Q_d = 0.976\, C_{qo}[1 + 0.1(h/t_s)^{0.95}](2r_d)^{0.2} h^{0.9} {k_s}^{0.74} \quad \text{Eqn. 5}$$

where:

Q_d = Flow rate through a single defect (L^3/T);
h = Pressure head of the liquid on top of the liner (L);
t_s = Thickness of the liner (L);
r_d = Radius of circular defect (L); and
k_s = Saturated hydraulic conductivity (L/T).

Here, C_{qo} is a unitless coefficient that varies in value depending on whether contact conditions are good (C_{qo} = 0.21) or poor (C_{qo} = 1.15). Good contact is when the GM has few wrinkles and the clay layer has a smooth surface. Poor contact is when the GM has many wrinkles and the clay layer has a rough surface. Importantly, the Giroud formula is semi-empirical and only valid when data are expressed in the following units: Q_d (m^3/s), i_s (unitless), r_d (m), h (m), k_s (m/s).

Giroud's (1997) formula is valid as long as three conditions are met. First, the defect diameter should fall between 0.5 mm and 25 mm. Second, h must be less than or equal to 3 meters. Third, k_s must not exceed k_G, which is defined as follows (Giroud, 1997, Eq. 25):

$$k_G = \left\{ \frac{0.3891(2r_d)^{1.8}}{C_{qo}[1+0.1(h/t_s)^{0.95}]h^{0.4}} \right\}^{1/0.74} \quad \text{Eqn. 6}$$

Eqn. 6 is an empirical relationship and, thus, the units for each parameter must match the units required in Eqn. 5.

2.1.2.2 Touze-Foltz *et al.*'s (1999) Formula for Flux Through a Circular Defect

Touze-Foltz *et al*. (1999, Eqn. 10-11, 15-17) presented an alternative solution to evaluate flow through a GM circular defect. The major difference between this approach and the Giroud (1997) approach is that Touze-Foltz *et al*. (1999) is an analytical solution to the differential equation describing the physics of fluid flow (Eqn. 7, 8, and 9); in contrast, the formula presented by Giroud (1997) was based on empirical observations.

$$Q_d = \pi {r_d}^2 k_s i_s - 2\pi r_d \theta \alpha C_Q [I_1(\alpha r_d) K_1(\alpha R) - I_1(\alpha R) K_1(\alpha r_d)] \quad \text{Eqn. 7}$$

$$C_Q = \frac{t_s + h - h_a}{K_1(\alpha R) I_0(\alpha r_d) + K_0(\alpha r_d) I_1(\alpha R)} \quad \text{Eqn. 8}$$

$$\alpha = \sqrt{\frac{k_s}{t_s \theta}}$$ Eqn. 9

where:

i_s = Hydraulic gradient (unitless);
R = Radius of the wetted area (L);
θ = Hydraulic transmissivity of the gap between the GM and the clay layer (L^2/T);
α = Analytical parameter defined above (unitless);
K_0 = Modified zero order Bessel function (unitless);
I_0 = Modified zero order Bessel function (unitless);
K_1 = Modified first order Bessel function (unitless);
I_1 = Modified first order Bessel function (unitless); and
C_{qo} = Dimensionless GM contact quality coefficient (0.21 for good and 1.15 for poor contact).

R is the radius of the wetted area and represents the validity limit of the solution; effectively, R is associated with the maximum distance between wrinkle defects and empirically ranges between 1.3 to 4.4 meters (Touze-Foltz *et al*., 1999). θ is the hydraulic transmissivity of the gap between the GM and the clay layer and can be determined experimentally. Alternatively, for a composite liner with a compacted clay layer, Rowe (2012) provides the following approaches to estimate θ where k_s is in m/s and θ is in m^2/s.

Good contact: $log_{10}\theta = 0.07 + 1.036(log_{10}k_s) + 0.0180(log_{10}k_s)^2$ Eqn. 10

Poor contact: $log_{10}\theta = 1.15 + 1.092(log_{10}k_s) + 0.0207(log_{10}k_s)^2$ Eqn. 11

2.1.2.3 Defect Density

The equations presented by Giroud (1997) and Touze-Foltz *et al*. (1999) define the total flow rate within a single defect. To determine the total flow rate across the entire GM, Q_{GM} (L^3/T), the flow rate though each defect must be multiplied by the defect density (D, in units of defects/L^2) and the liner area (A in units of L^2) as outlined below.

$$Q_{GM} = Q_d \times D \times A$$ Eqn. 12

Or, expressed in terms of the unit flow rate,

$$q = \frac{Q}{A} = Q_d \times D$$ Eqn. 13

Touze-Foltz *et al*. (1999) reported that GMs in composite liners typically have between 2 and 26 defects per hectare after installation.

2.2 Travel Time

The time required for leachate to flow through a liner system is an important additional metric to evaluate performance.[1] A liner performs better when time for fluids to migrate through the system is large. This concept is illustrated in US EPA's Criteria for Identifying Areas of Vulnerable Hydrogeology Under the Resource Conservation and Recovery Act (US EPA, 1986). In this document, US EPA defined a groundwater system as potentially vulnerable when the travel time for fluids to migrate 100 feet through the unsaturated and saturated environment is less than 100 years.

Under saturated conditions, a simple transit time equation can be used to estimate travel time across the liner depth, t_s, based on Darcy's Law (Eqn. 14):

$$T = \frac{\phi \cdot t_s}{q} \qquad \text{Eqn. 14}$$

where:

T = Travel time (T);
q = Specific discharge (L/T), calculated by Equation 3;
ϕ = Effective porosity of the liner material (unitless); and
t_s = Thickness of the liner (L).

In turn, Equations 3 and 14 can be rearranged to estimate the depth to which fluids penetrate into a liner, L_s, during the operational period of a surface impoundment:

$$L_s = 0.5\left\{\frac{k_s T}{\phi} + \left[\left(\frac{k_s T}{\phi}\right)^2 + \frac{4k_s Th}{\phi}\right]^{1/2}\right\} \qquad \text{Eqn. 15}$$

where:

L_s = Fluid penetration depth (L);
k_s = Saturated hydraulic conductivity (L/T);
T = Time of surface impoundment operation (T);
ϕ = Effective porosity of the liner material (unitless); and
h = Hydraulic head in overlying impoundment (L).

However, this simple transit time approach ignores the initial unsaturated nature of the liner and infiltration dynamics. Green and Ampt (1911, as cited in US EPA, 1988) described the process of fluid infiltration in unsaturated soils resulting from overlying impoundments. The approach assumes a sharp, saturated wetting front moving down the soil/liner column. Above the wetting front, the soil/liner is fully saturated, while below the wetting front, the moisture content is equal to its lower, initial moisture content. The required time for the wetting front to reach to a given depth, L_s, is given by (US EPA, 1988):

$$T = \frac{\Theta_s - \Theta_i}{k_s}\left[L_s - (h + \Psi_c)\ln\left(1 + \frac{L}{\mathrm{h} + \Psi_c}\right)\right] \qquad \text{Eqn. 16}$$

[1] For a composite liner, the travel time for fluids to flow through the liner is controlled by the depth and hydraulic conductivity of the compacted soil component of the liner.

where:

T = Time (T);
Θ_s = Saturated water content (unitless);
Θ_i = Initial water content (unitless);
k_s = Saturated hydraulic conductivity (L/T);
L_s = Penetration distance of wetting front (L);
h = Hydraulic head in overlying impoundment (L); and
Ψ_c = Capillary suction under the liner (L).

Equation 16 can be used to calculate the time required for the wetting front to penetrate the entire liner by setting k_s equal to the liner hydraulic conductivity and L equal to the liner thickness. If the time for the wetting front to penetrate the full liner thickness is less than the expected operational life of the surface impoundment, the use of the simplified transit time approach (Eqn. 14) may be reasonable for an operating surface impoundment. However, if the wetting front has not penetrated the entire liner thickness during the period of surface impoundment operation, which is likely for thick natural clay-lined scenarios, the travel time calculations must account for the transient hydraulic heads that occur during and after impoundment operation. Even after impoundment closure, the wetting front will continue to migrate vertically downward due to gravity; however, the rate of migration will slow without the overlying hydraulic head.

Additionally, as the wetting front migrates downward into previously unsaturated soils, a portion of the water is retained by capillary forces on the clay soil particles. Water is retained at its residual saturation value; water's residual saturation in clay soils typically ranges from 0.25 to 0.57% (Brooks and Corey, 1964). Furthermore, the volume of water migrating downward declines over time as it becomes trapped in the clay pore space. If the unsaturated portion of the clay liner is thick enough, and has sufficient pore space capacity, a wetting front may never migrate entirely through the liner. A fluid conservation model can be used to estimate the thickness of a clay liner, below the penetration depth calculated in Eqn. 15, that is required to entrap all fluids that have infiltrated into the liner from the overlying impoundment (Eqn. 17).

$$L_r = \frac{L_s \times \Theta_s}{\Theta_r - \Theta_i} \qquad \text{Eqn. 17}$$

where:

L_r = Clay thickness, below the penetration depth, required to entrap all fluids (L);
L_s = Penetration distance of wetting front (L);
Θ_s = Saturated water content (unitless);
Θ_i = Initial water content (unitless); and
Θ_r = Residual saturation of water in clay (unitless).

If the unsaturated clay liner thickness overlying groundwater is greater than the calculated value of L_r in Equation 17, all water that infiltrates into the liner from an overlying impoundment will be trapped by the capillary forces and, thus, no water from the overlying impoundment will penetrate the entire depth of the liner.

3 Liner Performance Evaluation Examples

The analytical equations described in Section 2 provide an approach by which the performance of various liners systems can be evaluated and compared. This section provides two examples of liner performance calculations for hypothetical surface impoundment liner systems. The first example compares the performance of a natural clay liner to a composite liner and the second example compares the performance of two composite liners, one that meets current federal design standards and one that does not. For both examples, liner performance is assessed using two criteria: hydraulic flux through the liner system, which is a surrogate for constituent mass that may be escaping the disposal facility, and travel time through the liner system, which is a metric that can be used to assess vulnerability of underlying groundwater resources.

3.1 Example 1: Performance Evaluation Comparison of Natural Clay Liner and Composite Liner

For the first example, liner performance was evaluated for both a natural clay liner and a composite liner. Details of the two liner systems are described below:

- An impoundment with a composite liner consisting of a 60 mil HDPE GM underlain by a 2-foot layer of compacted soil with a hydraulic conductivity of 1×10^{-7} cm/s. This liner meets the federal liner system design criteria contained in 40 CFR 257.70(b).
- An impoundment that has no engineered liner but does have a natural clay liner that is 50 feet thick, with an average hydraulic conductivity of 1×10^{-8} cm/s. This liner does not meet current federal liner system design criteria.

For both liner systems, a head on the liner system ranging from 0.5 to 3 meters was assumed. For the composite-lined system, circular GM defects occurring at frequency ranging from 2 to 26 defects per hectare (Touze-Foltz *et al*., 1999) with an average diameter of 5 mm were also assumed. Hydraulic flux was calculated for a range of values for contact quality factor (C_{qo}), which is an empirical parameter relating to the quality of the GM installation and the contact with the underlying compacted soil layer. Good contact (*i.e*., low C_{qo}) corresponds to GMs installed with few wrinkles and placed on a smooth compacted soil layer; poor contact (*i.e*., high C_{qo}) corresponds to GMs installed with wrinkles and placed on a compacted soil layer that has not been well compacted and/or is not smooth.

Flux was estimated using Equation 5 for the composite-lined system (Tables 3.1 and 3.2) and Equation 3 for the natural clay-lined system (Table 3.3) assuming fully saturated, steady-state conditions for each liner system. The calculated flux for a composite-lined system ranges from 1.6 liters/hectare-day (lphd) for systems installed with good contact and a low defect frequency to 747 lphd for systems installed with poor contact and a high defect frequency. The calculated flux for a natural clay-lined system ranges from 89 to 103 lphd. These results indicate that the hydraulic performance of the natural clay-lined system is comparable to the performance of the composite-lined system. As a comparison, the hydraulic flux through an engineered clay liner system (2 feet of clay with a hydraulic conductivity of 1×10^{-7} cm/s) with 0.5 to 3 meters of overlying hydraulic head, ranges from 1,572 to 5,115 lphd, one to two orders of magnitude higher than the calculated flux through both the composite-lined and natural clay-lined systems.

Table 3.1 Estimated Hydraulic Flux Through Composite Liner System – Good Contact Quality (C_{qo} = 0.21)

Surface Impoundment Head	Hydraulic Flux (liters/hectare-day)	
	2 Defects per Hectare	26 Defects per Hectare
h = 0.5 meters	1.6	20
h = 1.5 meters	4.8	62
h = 3 meters	10	136

Table 3.2 Estimated Hydraulic Flux Through Composite Liner System – Poor Contact Quality (C_{qo} = 1.15)

Surface Impoundment Head	Hydraulic Flux (liters/hectare-day)	
	2 Defects per Hectare	26 Defects per Hectare
h = 0.5 meters	8.5	111
h = 1.5 meters	26	340
h = 3 meters	57	747

Table 3.3 Estimated Hydraulic Flux Through Natural Clay-lined System

Surface Impoundment Head	Hydraulic Flux (liters/hectare-day)
h = 0.5 meters	89
h = 1.5 meters	95
h = 3 meters	103

The second metric we have used to evaluate liner system performance is travel time. The estimated time of travel for fluids to migrate through the composite and natural clay-lined systems was calculated using Darcy's Law (Eqn. 3) and the simplified transit equation presented in Equation 14. For these calculations, a unit hydraulic gradient (*i.e.*, no overlying impounded water, h = 0 in Eqn. 3) and a porosity of 40% were assumed. For the composite-lined system, the calculated seepage velocity of fluids migrating through the secondary 2-foot compacted soil liner (hydraulic conductivity of 1×10^{-7} cm/s) is 0.26 ft/year. For the natural clay-lined system, the calculated seepage velocity of fluids migrating through the 50-foot natural clay layer (hydraulic conductivity of 1×10^{-8} cm/s) is 0.03 ft/year. Thus, the total travel time for fluids to migrate through the composite liner is about 7.7 years and the total travel time for fluids to migrate through the natural clay liner is greater than 1,600 years.

The 1,600 year travel time through the natural clay liner is a conservative estimate based on full saturation of the entire 50-foot liner. If we assume a 3-meter head on top of the liner system and 30 years of surface impoundment operation, the penetration depth of the wetting front during impoundment operation given by Equation 15 is 3.2 feet. As discussed in Section 2.2, the rate and volume of fluid migration through the liner when the surface impoundment is inactive and dewatered depends on the initial and residual moisture contents and the capillary pressure in the clay formation (see Equations 16 and 17). In this example, reasonably assuming that the initial moisture content of the clay layer is 10% (*i.e.*, 10% of the volume of voids between clay grains are filled with water), the residual saturation of water in the clay is 20%, and the full saturation moisture content is 100%, the total penetration depth of water into the natural clay liner is 29 feet (Eqn. 17). Thus, assuming that no additional water enters the liner after surface impoundment closure (*e.g.*, precipitation), water from the overlying surface impoundment will not migrate completely through the natural clay liner.

Overall, based on an evaluation of hydraulic flux and travel time in this example, performance of the natural clay liner exceeded performance of the composite liner.

3.2 Example 2: Performance Evaluation Comparison of Two Different Composite Liners

For the second example, liner performance was evaluated for two different composite liners. Details of the two liner systems are described below:

- An impoundment with a composite liner consisting of a 60 mil HDPE GM underlain by a 2-foot layer of compacted soil with a hydraulic conductivity of 1×10^{-7} cm/s. This liner meets the federal liner system design criteria contained in 40 CFR 257.70(b).
- An impoundment with a composite liner consisting of a 30 mil HDPE GM underlain by a 2-foot layer of compacted soil with a hydraulic conductivity of 1×10^{-8} cm/s. This liner does not meet the federal liner system design criteria contained in 40 CFR 257.70(b) because the GM does meet the federal GM thickness standard. However, the secondary compacted soil layer exceeds federal standards.

For both composite liner systems, we assumed a head of 3 meters on the liner and assumed that both GMs were installed with a good contact quality (*e.g.*, $C_{qo} = 0.21$). For both liner systems, we also assumed circular GM defects with an average diameter of 5 mm. However, we assumed that the 30 mil HDPE GM is more prone to manufacturing and installation defects than the 60 mil GM because of the differences in thickness. For the 60 mil HDPE GM, we assumed 5 defects per hectare, and for the 30 mil HDPE GM, we assumed 15 defects per hectare. The defect density for both liners is within the range cited in Touze-Foltz *et al*. (1999).

Flux was estimated using Equation 5 for both composite-lined systems (Tables 3.4). The calculated flux for the composite-lined system with a 60 mil HDPE GM and a 1×10^{-7} cm/s hydraulic conductivity secondary soil layer, which meets the federal liner system design criteria, is 26 lphd. The calculated flux for the composite-lined system with a 30 mil HDPE GM and a 1×10^{-8} cm/s hydraulic conductivity secondary soil layer, which does not meet the federal liner system design criteria, is 14 lphd.

Table 3.4 Estimated Hydraulic Flux Through Two Composite Liner Systems

Composite Liner Description	Hydraulic Flux (liters/hectare-day)
60 mil HDPE GM with a 1×10^{-7} cm/s hydraulic conductivity secondary soil layer	26
30 mil HDPE GM with a 1×10^{-8} cm/s hydraulic conductivity secondary soil layer	14

The estimated time of travel for fluids to migrate through the two composite-lined systems was calculated using Darcy's Law (Eqn. 3) and the simplified transit equation presented in Equation 14. For these calculations, a porosity of 40% was assumed. For the composite-lined system with a 60 mil HDPE GM and 1×10^{-7} cm/s hydraulic conductivity secondary layer, the calculated seepage velocity of fluids migrating through the secondary 2-foot compacted soil liner is 1.5 ft/year. At this velocity, water would penetrate the secondary soil layer in 1.3 years. For the composite-lined system with a 30 mil HDPE GM and 1×10^{-8} cm/s hydraulic conductivity secondary layer, the calculated seepage velocity of fluids migrating through the secondary 2-foot compacted soil liner is 0.15 ft/year. At this velocity, water would penetrate the secondary soil layer in 13.3 years.

Overall, based on an evaluation of hydraulic flux and travel time in this example, performance of the alternate composite liner that does not meet current federal liner design criteria exceeded performance of the composite liner that does meet federal liner design criteria.

4 Data Requirements for Demonstrating Sustainability of Natural Clay Liners

In preceding sections, we demonstrated that an alternative liner system, including natural clay liners, can perform equivalently to, or better than, composite-lined systems. However, while a composite liner system can be installed with continuous oversight and a thorough construction quality assurance (CQA) program in order to reduce potential for defects, the only way to demonstrate that a natural clay liner will meet performance expectations is through a strong data collection and field investigation program. This section describes the types of data that may be used to demonstrate the suitability of a natural clay liner. Two types of data and analyses relating to the characterization of the clay geology and groundwater quality are presented in this section and can help inform evaluations of whether a natural clay liner system will meet performance expectations that are comparable to a composite liner.

4.1 Characterization of the Clay Geologic Environment

The effectiveness of a natural clay liner system depends on several factors, the most important of which are the permeability of the clay material and quality of the clay layer. Clay has unique chemical and electrostatic properties that influence its permeability and make it an effective liner material. However, natural clays are sometimes heterogeneous and may contain sand or gravel strata, organic matter, lenses of gypsum, limestone or other transmissive material, and cracks. Discontinuities such as these when present in a natural clay liner create preferential pathways for fluid migration and may lead to increased water fluxes or shorter travel time from the overlying disposal facility into the underlying groundwater. Thus, a thorough characterization of the clay geologic environment is necessary to ensure that a natural clay liner can reasonably meet or exceed the performance expectations that are comparable to a composite liner.

Soil borings should be drilled across the site to characterize the natural clay layer. Soil borings can be used to determine the specific thickness and variability of the natural clay layer across the site. The presence of lithologic materials such as sand or gravel strata, organic matter, lenses of gypsum, limestone, or other transmissive materials that may provide a preferential pathway between an impoundment and the underlying groundwater can also be determined with soil borings. In some cases, it may be appropriate to dig test pits and trenches to further identify and investigate the prevalence of features that may decrease the effectiveness of a natural clay liner. While the amount of data required varies depending on the size of the surface impoundment and how well characterized the regional environment is, sufficient borings and subsurface investigations should be performed based on site-specific conditions in order to make an informed decision regarding whether the natural clay liner can meet or exceed performance expectations that are comparable to a composite liner.

In-situ and/or laboratory tests should also be performed on clay samples from various depths to determine whether a natural clay liner will meet or exceed performance specifications that are comparable to a composite liner. Typically, this is performed by analyzing the permeability and hydraulic conductivity of the clay materials. Grain size analyses and Atterberg tests can also be useful in evaluating clay performance and locating potential heterogeneities. A significant change in Atterberg limits usually reflects a change in important engineering properties, such as the relationship among moisture content,

density, and permeability (US EPA, 1986), which can indicate a difference in lithological conditions and/or the presence of a preferential flow pathway in the natural clay.

4.2 Characterization of Groundwater Quality

In addition to characterizing the geologic environment of the natural clay liner, it is also important to characterize groundwater quality underlying the natural clay liner. Detection monitoring performed to determine indications of a release to groundwater is a long-term program that must be continued as long as a release is considered a potential risk. By monitoring groundwater, leaks through a natural clay liner may be identified, even if specific pathways for the leakage in the natural clay have not been determined. In order to evaluate groundwater quality beneath and downgradient of a disposal facility, a network of groundwater monitoring locations must be developed and installed. While the number and location of monitoring wells will vary depending on site-specific circumstances, including the size of the impoundment and hydrogeological conditions, the monitoring network should include multiple wells located upgradient and downgradient of the facility.

The CCR Rule (US EPA, 2015) presented monitoring program requirements that are designed to identify if releases from a disposal facility impact groundwater. This program requires installation of a groundwater monitoring system that consists of a sufficient number of wells installed at appropriate locations and depths to yield groundwater samples from the uppermost aquifer. The collected samples must accurately represent the quality of background water, as well as the quality of groundwater at the boundary of the CCR unit. The CCR Rule specifically requires the analysis of groundwater for typical coal ash constituents (*i.e.*, Appendix III constituents). For natural clay-lined sites, statistically significant increases (SSIs) of any constituent on the Appendix III list above the site-specific background concentration may be an indication that a release has penetrated the natural clay liner.

Other geochemical analyses, including but not limited to stable isotope analyses, tritium age dating, and trilinear piper diagrams, may also be useful by comparing the groundwater geochemistry downgradient and upgradient of a facility with the geochemistry of the impounded water. These analyses provide an indication of whether there may be mixing of different water types and sources – a sign that the natural clay liner may be leaking.

Overall, at sites where disposal facilities are lined by natural clays, the collection of site-specific data, including a characterization of both the natural clay geology and groundwater quality, is essential to determine whether a natural clay liner system can meet performance expectations that are comparable to a composite liner. These analyses that include field and laboratory methods are recognized and generally accepted good engineering practices consistent with CCR Rule requirements.

5 Conclusions

In August 2018, the United States Court of Appeals for the District of Columbia vacated portions of the CCR Rule related to the liner criteria. The Court decision was based on information contained in US EPA's 2014 Human and Ecological Risk Assessment of Coal Combustion Residuals (US EPA, 2014), which indicated that clay-lined impoundments were more likely to leak than composite-lined impoundments. As a result, only composite-lined systems, as described in 40 CFR 257.70(b), meet minimum federal liner standards. Consequently, some impoundments that were formerly considered lined do not meet federal standards and are subject to closure requirements.

This study presents a methodology demonstrating how liner performance can be evaluated based on both hydraulic flux through the liner and travel times. The method used for estimating leakage rate and time from clay liners is a widely accepted method that was referenced by US EPA in the CCR Rule, and the methods presented for estimating leakage through composite liners are widely known and used by practitioners. These methods are recognized and generally accepted good engineering practices consistent with requirements under the CCR Rule.

Additionally, in this report, we applied the methodology to compare the performance of a composite liner and several alternate liners that do not meet current federal liner design criteria. We used typical ranges of values for parameters that control leakage and evaluated performance through each liner system. Results of our analysis indicate that certain alternative liner systems, such as natural clay liners and alternate composite liners, perform comparable to, or better than, composite-lined systems that meet current federal liner design criteria.

With the comparative methodology presented in this report, a QPE would be able to certify a demonstration for an alternative liner system that:

- Defines the alternative liner system for which comparative performance requirements would be applied;
- Characterizes the alternative liner system by evaluating regional geology through available literature, site-specific characteristics, and subsurface investigations and field and laboratory testing;
- Calculates and compares the water flux between the defined alternative liner system and a composite liner system that meets current federal liner design criteria; and
- Calculates and compares the travel time between the defined alternative liner system and a composite liner system that meets current federal liner design criteria.

A QPE would be able to determine, on a site-specific basis, if the alternative liner system does not pose a reasonable probability of adverse effects to health or the environment if the comparative analysis demonstrates that the alternative liner system has comparable calculated water flux and travel times to a composite liner system that meets current federal liner design criteria.
